1 Machine Learning Engineer Nanodegree

1.1 Unsupervised Learning

1.2 Project: Creating Customer Segments

Welcome to the third project of the Machine Learning Engineer Nanodegree! In this notebook, some template code has already been provided for you, and it will be your job to implement the additional functionality necessary to successfully complete this project. Sections that begin with **'Implementation'** in the header indicate that the following block of code will require additional functionality which you must provide. Instructions will be provided for each section and the specifics of the implementation are marked in the code block with a `'TODO'` statement. Please be sure to read the instructions carefully!

In addition to implementing code, there will be questions that you must answer which relate to the project and your implementation. Each section where you will answer a question is preceded by a **'Question X'** header. Carefully read each question and provide thorough answers in the following text boxes that begin with **'Answer:'**. Your project submission will be evaluated based on your answers to each of the questions and the implementation you provide.

> **Note:** Code and Markdown cells can be executed using the **Shift + Enter** keyboard shortcut. In addition, Markdown cells can be edited by typically double-clicking the cell to enter edit mode.

1.3 Getting Started

In this project, you will analyze a dataset containing data on various customers' annual spending amounts (reported in *monetary units*) of diverse product categories for internal structure. One goal of this project is to best describe the variation in the different types of customers that a wholesale distributor interacts with. Doing so would equip the distributor with insight into how to best structure their delivery service to meet the needs of each customer.

The dataset for this project can be found on the UCI Machine Learning Repository. For the purposes of this project, the features `'Channel'` and `'Region'` will be excluded in the analysis — with focus instead on the six product categories recorded for customers.

Run the code block below to load the wholesale customers dataset, along with a few of the necessary Python libraries required for this project. You will know the dataset loaded successfully if the size of the dataset is reported.

In [1]:
```
# Import libraries necessary for this project
import numpy as np
import pandas as pd
from IPython.display import display # Allows the use of display() for DataFrames

# Import supplementary visualizations code visuals.py
import visuals as vs

# Pretty display for notebooks
%matplotlib inline

# Load the wholesale customers dataset
try:
    data = pd.read_csv("customers.csv")
    data.drop(['Region', 'Channel'], axis = 1, inplace = True)
    print("Wholesale customers dataset has {} samples with {} features each.".format(*da
except:
    print("Dataset could not be loaded. Is the dataset missing?")
```

```
Wholesale customers dataset has 440 samples with 6 features each.
```

1.4 Data Exploration

In this section, you will begin exploring the data through visualizations and code to understand how each feature is related to the others. You will observe a statistical description of the dataset, consider the relevance of each feature, and select a few sample data points from the dataset which you will track through the course of this project.

Run the code block below to observe a statistical description of the dataset. Note that the dataset is composed of six important product categories: **'Fresh'**, **'Milk'**, **'Grocery'**, **'Frozen'**, **'Detergents_Paper'**, and **'Delicatessen'**. Consider what each category represents in terms of products you could purchase.

In [2]:
```
# Display a description of the dataset
display(data.describe())
```

```
                Fresh          Milk       Grocery        Frozen  \
count      440.000000    440.000000    440.000000    440.000000
mean     12000.297727   5796.265909   7951.277273   3071.931818

25%           256.750000    408.250000
50%           816.500000    965.500000
75%          3922.000000   1820.250000
max         40827.000000  47943.000000
```

1.4.1 Implementation: Selecting Samples

To get a better understanding of the customers and how their data will transform through the analysis, it would be best to select a few sample data points and explore them in more detail. In the code block below, add **three** indices of your choice to the `indices` list which will represent the customers to track. It is suggested to try different sets of samples until you obtain customers that vary significantly from one another.

```
In [3]: # TODO: Select three indices of your choice you wish to sample from the dataset
        indices = [3, 7,9]

        # Create a DataFrame of the chosen samples
        samples = pd.DataFrame(data.loc[indices], columns = data.keys()).reset_index(drop = True
        print("Chosen samples of wholesale customers dataset:")
        display(samples)
```

```
Chosen samples of wholesale customers dataset:
```

	Fresh	Milk	Grocery	Frozen	Detergents_Paper	Delicatessen
0	13265	1196	4221	6404	507	1788
1	7579	4956	9426	1669	3321	2566
2	6006	11093	18881	1159	7425	2098

1.4.2 Question 1

Consider the total purchase cost of each product category and the statistical description of the dataset above for your sample customers.

- What kind of establishment (customer) could each of the three samples you've chosen represent?

Hint: Examples of establishments include places like markets, cafes, delis, wholesale retailers, among many others. Avoid using names for establishments, such as saying *"McDonalds"* when describing a sample customer as a restaurant. You can use the mean values for reference to compare your samples with. The mean values are as follows:

- Fresh: 12000.2977
- Milk: 5796.2
- Grocery: 3071.9

- Detergents_paper: 2881.4
- Delicatessen: 1524.8

Knowing this, how do your samples compare? Does that help in driving your insight into what kind of establishments they might be?

**Answer:

The customer type repesented by the indices 0 spend more money on the fresh category than either of its other categories, and more than that of each of the other respective categories. However indices 0 spends less in each of the remaining categories except the frozen category compared to the other indices. This suggest that this buisness makes the overwhelming portion of its profits from fresh goods and frozen like a juice bar, salad shop or ice cream parlor.

Indices 1 is the highest spender in the delicatessen category despite indices 2 spending almost double in the milk, grocery & detergents_paper categories. Indices 1's spending suggest that it is selling a high volume of deli items which suggest it could be a sandwich restaurant.

Indices 2 is characterized by its detergents and paper spending which is much more than the other two cases. This company could be grocery store or some type of wholesaler of goods.**

1.4.3 Implementation: Feature Relevance

One interesting thought to consider is if one (or more) of the six product categories is actually relevant for understanding customer purchasing. That is to say, is it possible to determine whether customers purchasing some amount of one category of products will necessarily purchase some proportional amount of another category of products? We can make this determination quite easily by training a supervised regression learner on a subset of the data with one feature removed, and then score how well that model can predict the removed feature.

In the code block below, you will need to implement the following: - Assign `new_data` a copy of the data by removing a feature of your choice using the `DataFrame.drop` function. - Use `sklearn.cross_validation.train_test_split` to split the dataset into training and testing sets. - Use the removed feature as your target label. Set a `test_size` of `0.25` and set a `random_state`. - Import a decision tree regressor, set a `random_state`, and fit the learner to the training data. - Report the prediction score of the testing set using the regressor's `score` function.

```
In [4]: # TODO: Make a copy of the DataFrame, using the 'drop' function to drop the given featur
        new_data = data.drop('Detergents_Paper', axis = 1)

        # TODO: Split the data into training and testing sets(0.25) using the given feature as t
        # Set a random state.
        from sklearn.cross_validation import train_test_split
        X_train, X_test, y_train, y_test = train_test_split(new_data, data['Detergents_Paper'],

        # TODO: Create a decision tree regressor and fit it to the training set
        from sklearn.tree import DecisionTreeRegressor
        regressor = DecisionTreeRegressor()

        model = regressor.fit(X_train, y_train)

        # TODO: Report the score of the prediction using the testing set
```

```
        y_pred = model.predict(X_test)

        Rsquared_score = model.score(X_test, y_pred)

        print('The predicted R-Squared score is: ',Rsquared_score)
```

```
The predicted R-Squared score is:  1.0
```

```
/opt/conda/lib/python3.6/site-packages/sklearn/cross_validation.py:41: DeprecationWarning: This
  "This module will be removed in 0.20.", DeprecationWarning)
```

1.4.4 Question 2

- Which feature did you attempt to predict?
- What was the reported prediction score?
- Is this feature necessary for identifying customers' spending habits?

Hint: The coefficient of determination, `R^2`, is scored between 0 and 1, with 1 being a perfect fit. A negative `R^2` implies the model fails to fit the data. If you get a low score for a particular feature, that lends us to beleive that that feature point is hard to predict using the other features, thereby making it an important feature to consider when considering relevance.

**Answer:

I chose to predict the Detergents_Paper category.

The reported prediction score was a R-squared value of 1.

The Detergents_Paper category has one of the highest variances accross the chosen indices, and seems like it can be used to indicate the scale of the business, which could provide insight into the type of business.

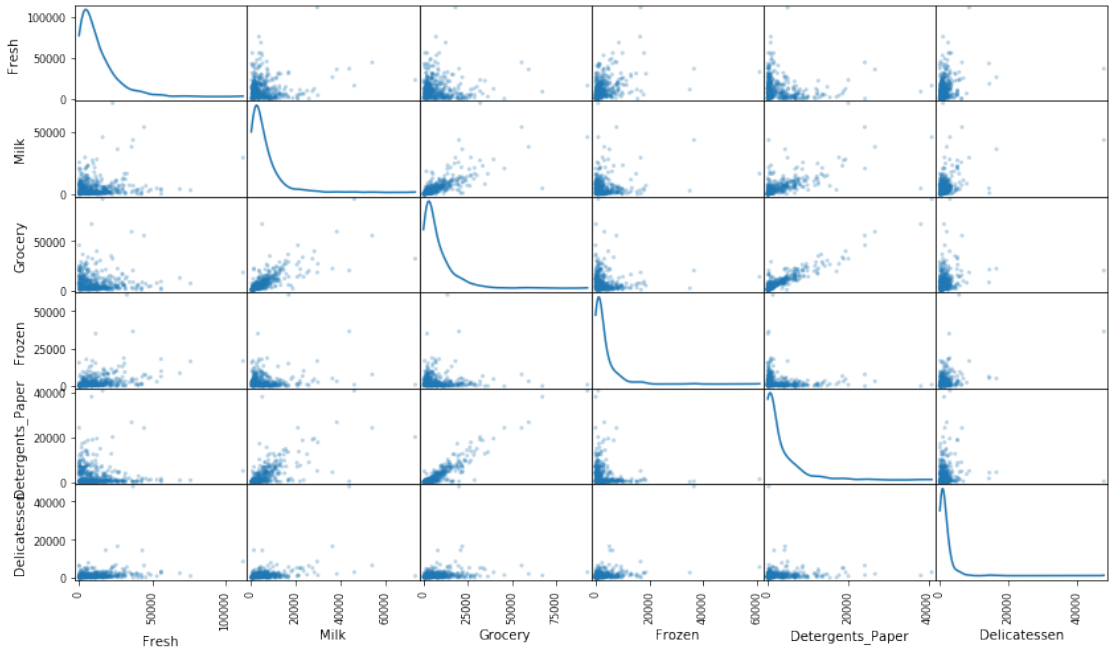
**

1.4.5 Visualize Feature Distributions

To get a better understanding of the dataset, we can construct a scatter matrix of each of the six product features present in the data. If you found that the feature you attempted to predict above is relevant for identifying a specific customer, then the scatter matrix below may not show any correlation between that feature and the others. Conversely, if you believe that feature is not relevant for identifying a specific customer, the scatter matrix might show a correlation between that feature and another feature in the data. Run the code block below to produce a scatter matrix.

```
In [5]: # Produce a scatter matrix for each pair of features in the data
        pd.scatter_matrix(data, alpha = 0.3, figsize = (14,8), diagonal = 'kde');
```

```
/opt/conda/lib/python3.6/site-packages/ipykernel_launcher.py:2: FutureWarning: pandas.scatter_ma
```



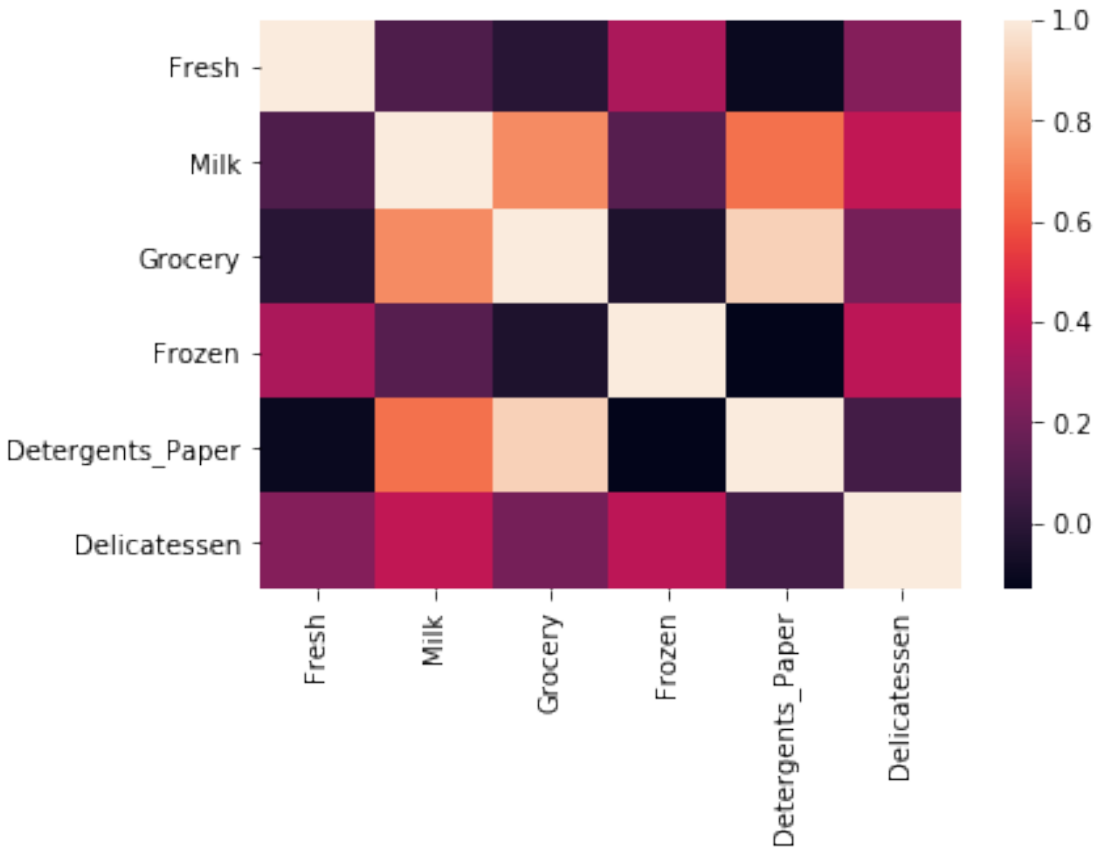
```
In [6]: display(data.corr())
```

```
                      Fresh      Milk   Grocery    Frozen  Detergents_Paper  \
Fresh              1.000000  0.100510 -0.011854  0.345881         -0.101953
Milk               0.100510  1.000000  0.728335  0.123994          0.661816
Grocery           -0.011854  0.728335  1.000000 -0.040193          0.924641
Frozen             0.345881  0.123994 -0.040193  1.000000         -0.131525
Detergents_Paper  -0.101953  0.661816  0.924641 -0.131525          1.000000
Delicatessen       0.244690  0.406368  0.205497  0.390947          0.069291

                  Delicatessen
Fresh                 0.244690
Milk                  0.406368
Grocery               0.205497
Frozen                0.390947
Detergents_Paper      0.069291
Delicatessen          1.000000
```

```
In [7]: from seaborn import heatmap
        heatmap(data.corr())
```

```
Out[7]: <matplotlib.axes._subplots.AxesSubplot at 0x7f811a9e0d68>
```



1.4.6 Question 3

- Using the scatter matrix as a reference, discuss the distribution of the dataset, specifically talk about the normality, outliers, large number of data points near 0 among others. If you need to sepearate out some of the plots individually to further accentuate your point, you may do so as well.
- Are there any pairs of features which exhibit some degree of correlation?
- Does this confirm or deny your suspicions about the relevance of the feature you attempted to predict?
- How is the data for those features distributed?

Hint: Is the data normally distributed? Where do most of the data points lie? You can use corr() to get the feature correlations and then visualize them using a heatmap (the data that would be fed into the heatmap would be the correlation values, for eg: `data.corr()`) to gain further insight.

Answer:

The scatter plots above indicate that all of the data in each of the respective categories are highly skewed to the left, and that the categories do not currently represent normal data, which would be indicated by a mean closer to zero and a more symmettrical graph.

The highest degree of correlation indicated between two products is between Detergents_Paper and Groceries, or that these products are purchased in similar proportions.

This confirms that at feature data will be useful in predicting the amount spent in the Detergents_paper category.

The data for both of those features is left skewed.

1.5 Data Preprocessing

In this section, you will preprocess the data to create a better representation of customers by performing a scaling on the data and detecting (and optionally removing) outliers. Preprocessing data is often times a critical step in assuring that results you obtain from your analysis are significant and meaningful.

1.5.1 Implementation: Feature Scaling

If data is not normally distributed, especially if the mean and median vary significantly (indicating a large skew), it is most often appropriate to apply a non-linear scaling — particularly for financial data. One way to achieve this scaling is by using a Box-Cox test, which calculates the best power transformation of the data that reduces skewness. A simpler approach which can work in most cases would be applying the natural logarithm.

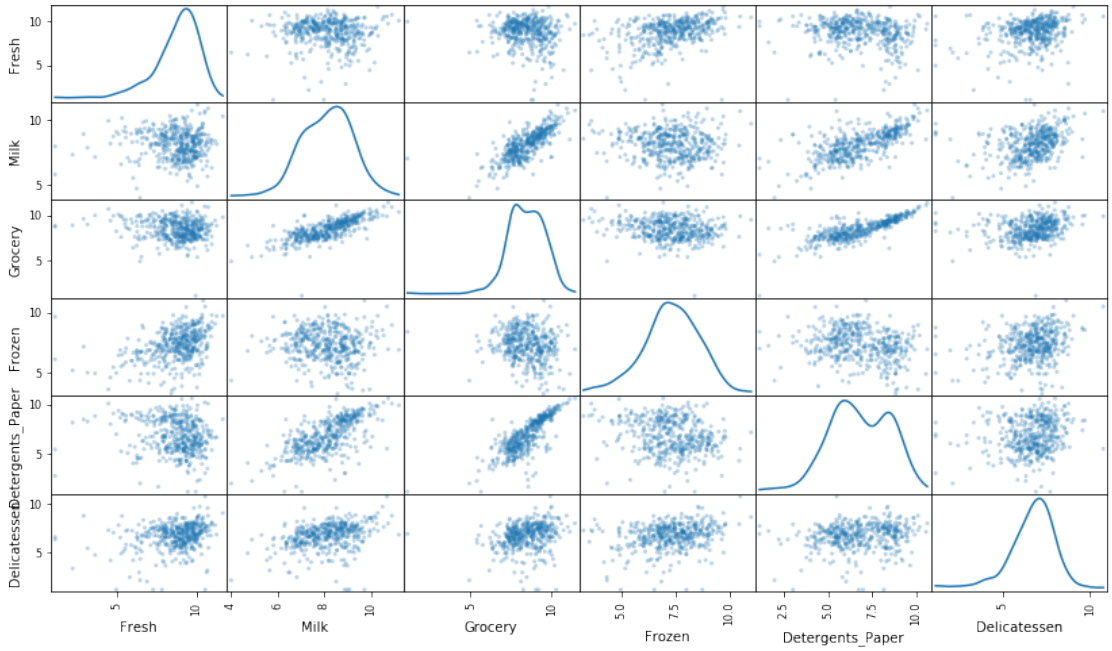
In the code block below, you will need to implement the following: - Assign a copy of the data to `log_data` after applying logarithmic scaling. Use the `np.log` function for this. - Assign a copy of the sample data to `log_samples` after applying logarithmic scaling. Again, use `np.log`.

In [8]:
```
# TODO: Scale the data using the natural logarithm
log_data = np.log(data)

# TODO: Scale the sample data using the natural logarithm
log_samples = np.log(samples)

# Produce a scatter matrix for each pair of newly-transformed features
pd.scatter_matrix(log_data, alpha = 0.3, figsize = (14,8), diagonal = 'kde');
```

```
/opt/conda/lib/python3.6/site-packages/ipykernel_launcher.py:8: FutureWarning: pandas.scatter_ma
```



1.5.2 Observation

After applying a natural logarithm scaling to the data, the distribution of each feature should appear much more normal. For any pairs of features you may have identified earlier as being correlated, observe here whether that correlation is still present (and whether it is now stronger or weaker than before).

Run the code below to see how the sample data has changed after having the natural logarithm applied to it.

```
In [9]: # Display the log-transformed sample data
        display(log_samples)
```

	Fresh	Milk	Grocery	Frozen	Detergents_Paper	Delicatessen
0	9.492884	7.086738	8.347827	8.764678	6.228511	7.488853
1	8.933137	8.508354	9.151227	7.419980	8.108021	7.850104
2	8.700514	9.314070	9.845911	7.055313	8.912608	7.648740

1.5.3 Implementation: Outlier Detection

Detecting outliers in the data is extremely important in the data preprocessing step of any analysis. The presence of outliers can often skew results which take into consideration these data points. There are many "rules of thumb" for what constitutes an outlier in a dataset. Here, we will use Tukey's Method for identfying outliers: An *outlier step* is calculated as 1.5 times the interquartile range (IQR). A data point with a feature that is beyond an outlier step outside of the IQR for that feature is considered abnormal.

In the code block below, you will need to implement the following: - Assign the value of the 25th percentile for the given feature to `Q1`. Use `np.percentile` for this. - Assign the value of the 75th percentile for the given feature to `Q3`. Again, use `np.percentile`. - Assign the calculation of an outlier step for the given feature to `step`. - Optionally remove data points from the dataset by adding indices to the `outliers` list.

NOTE: If you choose to remove any outliers, ensure that the sample data does not contain any of these points!
Once you have performed this implementation, the dataset will be stored in the variable `good_data`.

```
In [10]: # For each feature find the data points with extreme high or low values
         for feature in log_data.keys():

             # TODO: Calculate Q1 (25th percentile of the data) for the given feature
             Q1 = np.percentile(log_data, 25)

             # TODO: Calculate Q3 (75th percentile of the data) for the given feature
             Q3 = np.percentile(log_data, 75)

             # TODO: Use the interquartile range to calculate an outlier step (1.5 times the int
             step = 1.5 * (Q3 - Q1)

             # Display the outliers
             print("Data points considered outliers for the feature '{}':".format(feature))
             display(log_data[~(log_data[feature] >= Q1 - step) & (log_data[feature] <= Q3 + ste

         # OPTIONAL: Select the indices for data points you wish to remove
         outliers  = [66, 289, 75]

         # Remove the outliers, if any were specified
         good_data = log_data.drop(log_data.index[outliers]).reset_index(drop = True)
```

```
Data points considered outliers for the feature 'Fresh':

1.5.4 Question 4

- Are there any data points considered outliers for more than one feature based on the definition above?
- Should these data points be removed from the dataset?
- If any data points were added to the `outliers` list to be removed, explain why.

** Hint: ** If you have datapoints that are outliers in multiple categories think about why that may be and if they warrant removal. Also note how k-means is affected by outliers and whether or not this plays a factor in your analysis of whether or not to remove them.

Answer:

The following, indices 66, 75 and 289 were all outliers in mutiple categories.

These data should be removed not only becasue they are outliers in one category but because by being identified as an outlier in multiple categories sugges that that company may be a buisness unique to the cluster it is helping to define.

1.6 Feature Transformation

In this section you will use principal component analysis (PCA) to draw conclusions about the underlying structure of the wholesale customer data. Since using PCA on a dataset calculates the dimensions which best maximize variance, we will find which compound combinations of features best describe customers.

1.6.1 Implementation: PCA

Now that the data has been scaled to a more normal distribution and has had any necessary outliers removed, we can now apply PCA to the `good_data` to discover which dimensions about the data best maximize the variance of features involved. In addition to finding these dimensions, PCA will also report the *explained variance ratio* of each dimension — how much variance within the data is explained by that dimension alone. Note that a component (dimension) from PCA can be considered a new "feature" of the space, however it is a composition of the original features present in the data.

In the code block below, you will need to implement the following: - Import `sklearn.decomposition.PCA` and assign the results of fitting PCA in six dimensions with `good_data` to `pca`. - Apply a PCA transformation of `log_samples` using `pca.transform`, and assign the results to `pca_samples`.

```
In [11]: # TODO: Apply PCA by fitting the good data with the same number of dimensions as featur
         from sklearn.decomposition import PCA

         pca = PCA(n_components = good_data.shape[1])

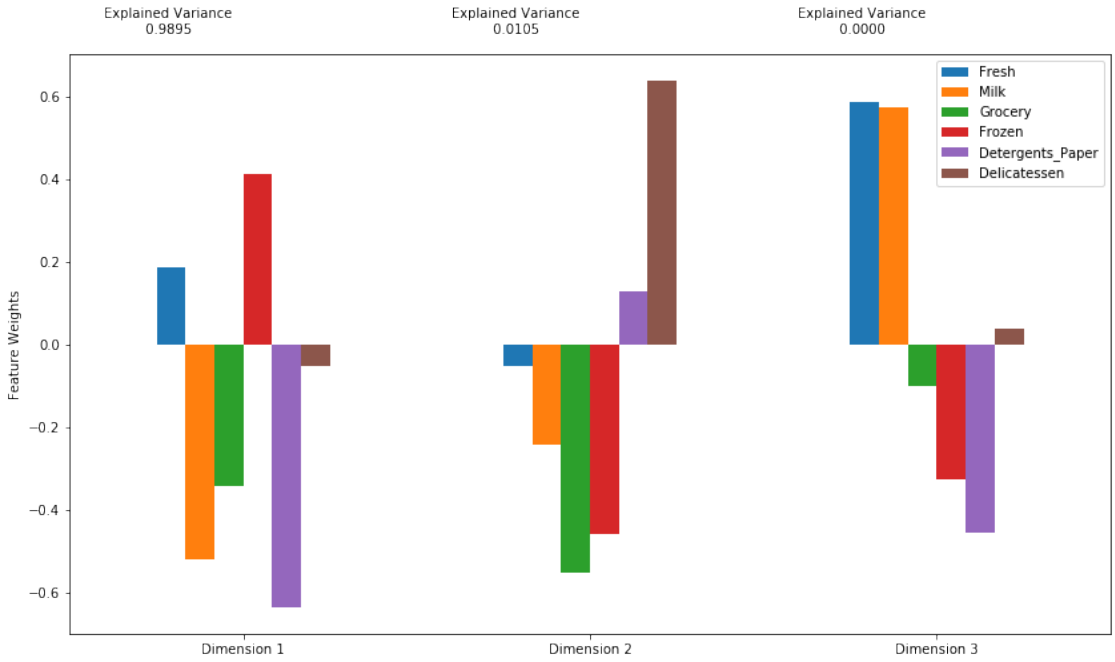
         # TODO: Transform log_samples using the PCA fit above
```

```
        pca_samples = pca.fit_transform(log_samples)

        # Generate PCA results plot
        pca_results = vs.pca_results(good_data, pca)

        print(pca.explained_variance_ratio_)
```

```
[  9.89526912e-01   1.04730884e-02   2.52955014e-31]
```



1.6.2 Question 5

- How much variance in the data is explained* **in total** *by the first and second principal component?
- How much variance in the data is explained by the first four principal components?
- Using the visualization provided above, talk about each dimension and the cumulative variance explained by each, stressing upon which features are well represented by each dimension(both in terms of positive and negative variance explained). Discuss what the first four dimensions best represent in terms of customer spending.

Hint: A positive increase in a specific dimension corresponds with an *increase* of the *positive-weighted* features and a *decrease* of the *negative-weighted* features. The rate of increase or decrease is based on the individual feature weights.

Answer:

99% percent of the variance in the data can be explained using only the first two principle componenets.

The remaining less than one percent variance can be explained with the third principal componenet.

The first principal component is characterized by large positive feature weights in the fresh and frozen categories, and large negative feature weights in the milk, grocery and detergents_paper categories.

The second principal component is characterized by negative fresh, milk, grocery and frozen feature weights, and positive detergents and delicatessen feature weights.

These resluts suggest along one dimension, the dimension dominating the explanation of variance, the fresh and frozen categories are positively correlated while the other categories are negatively correlated. In the secon dimension there is a much less pronounced positive relationship between detergents and delicatessen products. However the relative proportion of that positve correlation is outweighted by the delicatessen category.

1.6.3 Observation

Run the code below to see how the log-transformed sample data has changed after having a PCA transformation applied to it in six dimensions. Observe the numerical value for the first four dimensions of the sample points. Consider if this is consistent with your initial interpretation of the sample points.

```
In [12]: # Display sample log-data after having a PCA transformation applied
         display(pd.DataFrame(np.round(pca_samples, 4), columns = pca_results.index.values))
```

	Dimension 1	Dimension 2	Dimension 3
0	2.3760	-0.0803	0.0
1	-0.5121	0.2518	0.0
2	-1.8639	-0.1715	0.0

1.6.4 Implementation: Dimensionality Reduction

When using principal component analysis, one of the main goals is to reduce the dimensionality of the data — in effect, reducing the complexity of the problem. Dimensionality reduction comes at a cost: Fewer dimensions used implies less of the total variance in the data is being explained. Because of this, the *cumulative explained variance ratio* is extremely important for knowing how many dimensions are necessary for the problem. Additionally, if a signifiant amount of variance is explained by only two or three dimensions, the reduced data can be visualized afterwards.

In the code block below, you will need to implement the following: - Assign the results of fitting PCA in two dimensions with `good_data` to `pca`. - Apply a PCA transformation of `good_data` using `pca.transform`, and assign the results to `reduced_data`. - Apply a PCA transformation of `log_samples` using `pca.transform`, and assign the results to `pca_samples`.

```
In [13]: # TODO: Apply PCA by fitting the good data with only two dimensions
         pca = PCA(n_components = 2)

         # TODO: Transform the good data using the PCA fit above
         reduced_data = pca.fit_transform(good_data)

         # TODO: Transform log_samples using the PCA fit above
```

```
        pca_samples = pca.fit_transform(log_samples)

        # Create a DataFrame for the reduced data
        reduced_data = pd.DataFrame(reduced_data, columns = ['Dimension 1', 'Dimension 2'])
```

1.6.5 Observation

Run the code below to see how the log-transformed sample data has changed after having a PCA transformation applied to it using only two dimensions. Observe how the values for the first two dimensions remains unchanged when compared to a PCA transformation in six dimensions.

```
In [14]: # Display sample log-data after applying PCA transformation in two dimensions
         display(pd.DataFrame(np.round(pca_samples, 4), columns = ['Dimension 1', 'Dimension 2']
```

	Dimension 1	Dimension 2
0	2.3760	-0.0803
1	-0.5121	0.2518
2	-1.8639	-0.1715

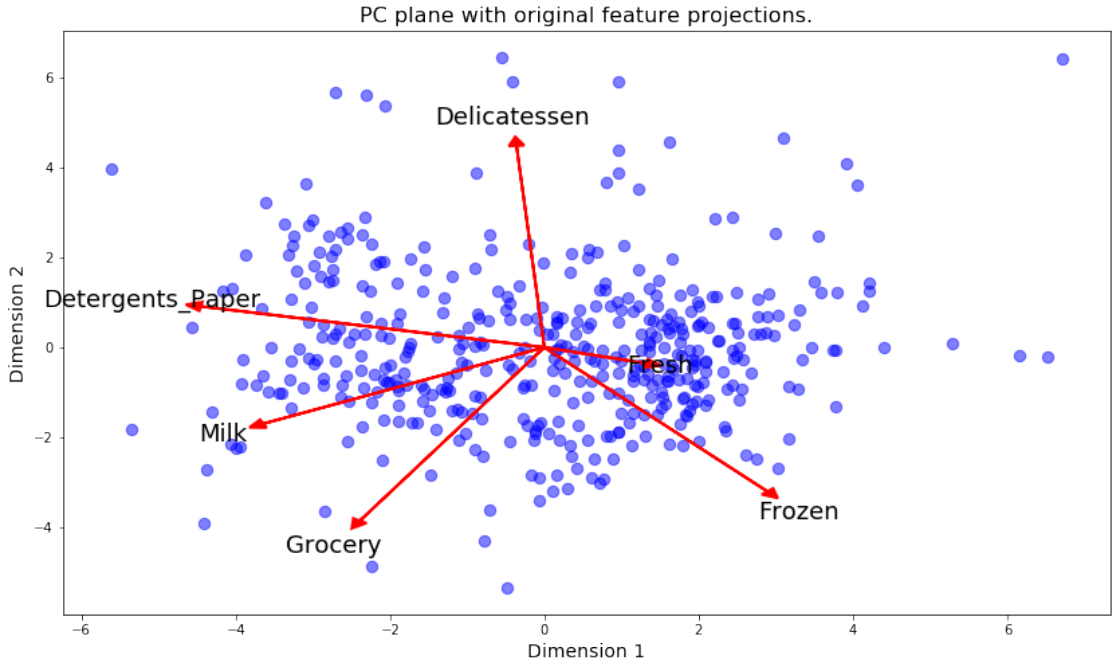
1.7 Visualizing a Biplot

A biplot is a scatterplot where each data point is represented by its scores along the principal components. The axes are the principal components (in this case `Dimension 1` and `Dimension 2`). In addition, the biplot shows the projection of the original features along the components. A biplot can help us interpret the reduced dimensions of the data, and discover relationships between the principal components and original features.

Run the code cell below to produce a biplot of the reduced-dimension data.

```
In [15]: # Create a biplot
         vs.biplot(good_data, reduced_data, pca)

Out[15]: <matplotlib.axes._subplots.AxesSubplot at 0x7f811b3b06a0>
```



1.7.1 Observation

Once we have the original feature projections (in red), it is easier to interpret the relative position of each data point in the scatterplot. For instance, a point the lower right corner of the figure will likely correspond to a customer that spends a lot on `'Milk'`, `'Grocery'` and `'Detergents_Paper'`, but not so much on the other product categories.

From the biplot, which of the original features are most strongly correlated with the first component? What about those that are associated with the second component? Do these observations agree with the pca_results plot you obtained earlier?

1.8 Clustering

In this section, you will choose to use either a K-Means clustering algorithm or a Gaussian Mixture Model clustering algorithm to identify the various customer segments hidden in the data. You will then recover specific data points from the clusters to understand their significance by transforming them back into their original dimension and scale.

1.8.1 Question 6

- What are the advantages to using a K-Means clustering algorithm?
- What are the advantages to using a Gaussian Mixture Model clustering algorithm?
- Given your observations about the wholesale customer data so far, which of the two algorithms will you use and why?

** Hint: ** Think about the differences between hard clustering and soft clustering and which would be appropriate for our dataset.

Answer:

K-means clustering is special case of Gaussian Mixture model where the covariance along one direction approaches 0. This results in a simpler, more efficient algorithm that will cluster the data in spherical clusters.

Gaussian Mixture model clustering allows the the model to find more nauced realtionships in the data and describe clusters that represent differnt shapes if that is what the data warrants. The Gaussian Mixture model also provides a proabaility that a specified point belongs to a particular cluster.

Due to the complexity of this data I will use the Gaussian Mixture Model algorithm to define clusters in this data.

Reference: https://quora.com/What-are-the-advantages-to-using-a-Gaussian-Mixture-Model-clustering-algorithm

1.8.2 Implementation: Creating Clusters

Depending on the problem, the number of clusters that you expect to be in the data may already be known. When the number of clusters is not known *a priori*, there is no guarantee that a given number of clusters best segments the data, since it is unclear what structure exists in the data — if any. However, we can quantify the "goodness" of a clustering by calculating each data point's *silhouette coefficient*. The silhouette coefficient for a data point measures how similar it is to its assigned cluster from -1 (dissimilar) to 1 (similar). Calculating the *mean* silhouette coefficient provides for a simple scoring method of a given clustering.

In the code block below, you will need to implement the following: - Fit a clustering algorithm to the `reduced_data` and assign it to `clusterer`. - Predict the cluster for each data point in `reduced_data` using `clusterer.predict` and assign them to `preds`. - Find the cluster centers using the algorithm's respective attribute and assign them to `centers`. - Predict the cluster for each sample data point in `pca_samples` and assign them `sample_preds`. - Import `sklearn.metrics.silhouette_score` and calculate the silhouette score of `reduced_data` against `preds`. - Assign the silhouette score to `score` and print the result.

In [16]:
```
# TODO: Apply your clustering algorithm of choice to the reduced data
from sklearn import mixture
from sklearn.metrics import silhouette_score

model = mixture.GaussianMixture(n_components = 2)

clusterer = model.fit(reduced_data)

# TODO: Predict the cluster for each data point
preds = clusterer.predict(reduced_data)

# TODO: Find the cluster centers
centers = model.means_
centers1 = clusterer.means_

print(centers)
#print(centers1)
```

```
        # TODO: Predict the cluster for each transformed sample data point
        pca_model = mixture.GaussianMixture(n_components = 2)

        pca_model = pca_model.fit(pca_samples)

        sample_preds = pca_model.predict(pca_samples)

        # TODO: Calculate the mean silhouette coefficient for the number of clusters chosen
        score = silhouette_score(reduced_data, preds)

        print(score)
```

```
[[ 1.26775117 -0.23753337]
 [-2.1802337   0.40850149]]
0.418477540996
```

1.8.3 Question 7

- Report the silhouette score for several cluster numbers you tried.
- Of these, which number of clusters has the best silhouette score?

Answer:

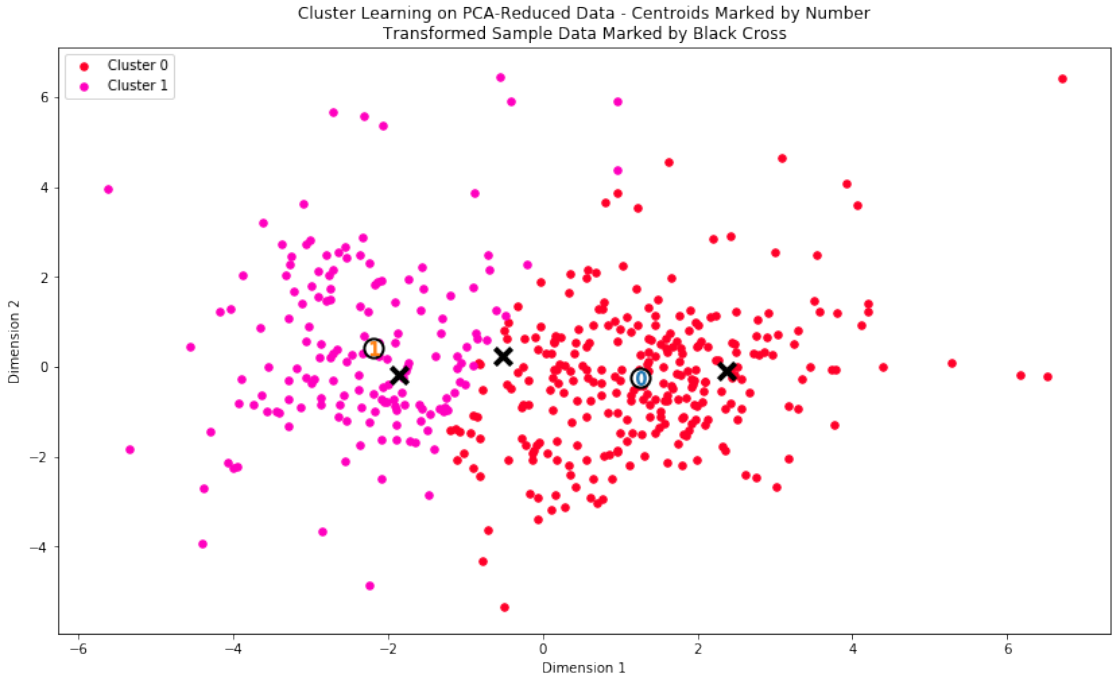
The silhoutte scores associated with the following numbers of clusters: 2 clusters: .4188 3 clusters: .4162 4 clusters: .3156 6 clusters: .2939 8 clusters: .3096

2 clusters represents the highest silhoutte score.

1.8.4 Cluster Visualization

Once you've chosen the optimal number of clusters for your clustering algorithm using the scoring metric above, you can now visualize the results by executing the code block below. Note that, for experimentation purposes, you are welcome to adjust the number of clusters for your clustering algorithm to see various visualizations. The final visualization provided should, however, correspond with the optimal number of clusters.

```
In [17]: # Display the results of the clustering from implementation
         vs.cluster_results(reduced_data, preds, centers, pca_samples)
```



1.8.5 Implementation: Data Recovery

Each cluster present in the visualization above has a central point. These centers (or means) are not specifically data points from the data, but rather the *averages* of all the data points predicted in the respective clusters. For the problem of creating customer segments, a cluster's center point corresponds to *the average customer of that segment*. Since the data is currently reduced in dimension and scaled by a logarithm, we can recover the representative customer spending from these data points by applying the inverse transformations.

In the code block below, you will need to implement the following: - Apply the inverse transform to `centers` using `pca.inverse_transform` and assign the new centers to `log_centers`. - Apply the inverse function of `np.log` to `log_centers` using `np.exp` and assign the true centers to `true_centers`.

```
In [18]: # TODO: Inverse transform the centers
         log_centers = pca.inverse_transform(centers)

         # TODO: Exponentiate the centers
         true_centers = np.exp(log_centers)

         # Display the true centers
         segments = ['Segment {}'.format(i) for i in range(0,len(centers))]
         true_centers = pd.DataFrame(np.round(true_centers), columns = data.keys())
         true_centers.index = segments
         display(true_centers)

             Fresh     Milk  Grocery  Frozen  Detergents_Paper  Delicatessen
```

```
Segment 0  10857.0   2211.0   6720.0  4354.0            1005.0        1712.0
Segment 1   5495.0  11362.0  15285.0   780.0            9790.0        3091.0
```

1.8.6 Question 8

- Consider the total purchase cost of each product category for the representative data points above, and reference the statistical description of the dataset at the beginning of this project(specifically looking at the mean values for the various feature points). What set of establishments could each of the customer segments represent?

Hint: A customer who is assigned to `'Cluster X'` should best identify with the establishments represented by the feature set of `'Segment X'`. Think about what each segment represents in terms their values for the feature points chosen. Reference these values with the mean values to get some perspective into what kind of establishment they represent.

Answer:

Segment 0 seems as if it represents a sort of restaurant or deli. The category centers depict a customer who spends most on fresh goods and the least on detergents and paper products. The amount that this the cluster center spends on detergrnts and paper is well below the average across all data points of 2,881.

Segement 1 seems as if it could represent a grocery store or food wholesaler. This segment is characterized by relatively high spend on both groceries and detergent and cleaning products.

1.8.7 Question 9

- For each sample point, which customer segment from* **Question 8** *best represents it?
- Are the predictions for each sample point consistent with this?*

Run the code block below to find which cluster each sample point is predicted to be.

```
In [19]: # Display the predictions
         for i, pred in enumerate(sample_preds):
             print("Sample point", i, "predicted to be in Cluster", pred)
```

```
Sample point 0 predicted to be in Cluster 0
Sample point 1 predicted to be in Cluster 1
Sample point 2 predicted to be in Cluster 1
```

Answer:

Cluster 1 “grocery store” cluster is chosen for two of the sample points. sample point 1 spent 9,426 and 3,321 on groceries and detergents respectively. of the three sample points this would have been the hardest to cluster. Graphically, the sample 2 point is within the region to be classified as a restaurant (cluster 0) but is right on the border where it could potentially be small grocery store, a large restaurant or pherpahs a small grocery with a place to eat.

1.9 Conclusion

In this final section, you will investigate ways that you can make use of the clustered data. First, you will consider how the different groups of customers, the ***customer segments***, may be affected differently by a specific delivery scheme. Next, you will consider how giving a label to each customer (which *segment* that customer belongs to) can provide for additional features about the customer data. Finally, you will compare the ***customer segments*** to a hidden variable present in the data, to see whether the clustering identified certain relationships.

1.9.1 Question 10

Companies will often run A/B tests when making small changes to their products or services to determine whether making that change will affect its customers positively or negatively. The wholesale distributor is considering changing its delivery service from currently 5 days a week to 3 days a week. However, the distributor will only make this change in delivery service for customers that react positively.

- How can the wholesale distributor use the customer segments to determine which customers, if any, would react positively to the change in delivery service?*

Hint: Can we assume the change affects all customers equally? How can we determine which group of customers it affects the most?

Answer:

In order to test out the new delivery changes, the company should choose a small subset of the two customer groups and document how the customers from each respective customer segment respond. We cannot assume that these two differnt segments will respond similarly becasue they have different businees needs. In the particular case, if the retailer customer segment is able to suppor 3 weekly deleiveries without adversely impacting the business then the company could reduces expenses and potentially validate this analysis.

1.9.2 Question 11

Additional structure is derived from originally unlabeled data when using clustering techniques. Since each customer has a ***customer segment*** it best identifies with (depending on the clustering algorithm applied), we can consider *'customer segment'* as an **engineered feature** for the data. Assume the wholesale distributor recently acquired ten new customers and each provided estimates for anticipated annual spending of each product category. Knowing these estimates, the wholesale distributor wants to classify each new customer to a ***customer segment*** to determine the most appropriate delivery service.

* How can the wholesale distributor label the new customers using only their estimated product spending and the **customer segment** data?

Hint: A supervised learner could be used to train on the original customers. What would be the target variable?

Answer:

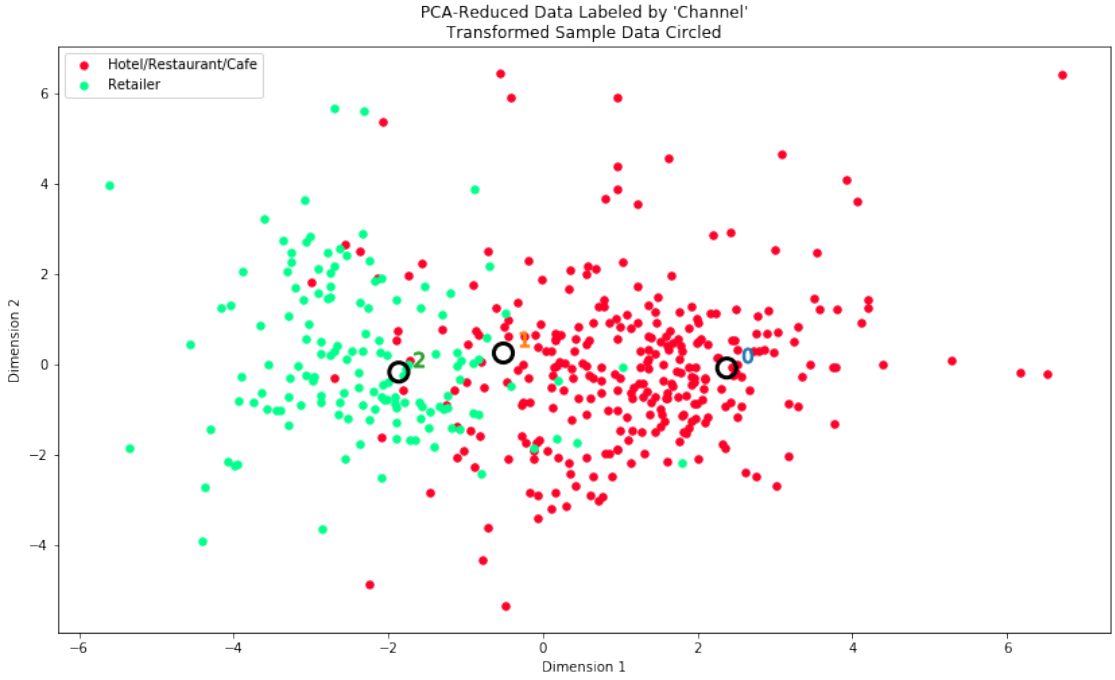
In order to complete this task. The predicted clusters would become labels. Then the best supervised learning algorithm can be trained on an tested or the sample data, and used to project which type of company the new companies will be based on their history.

1.9.3 Visualizing Underlying Distributions

At the beginning of this project, it was discussed that the `'Channel'` and `'Region'` features would be excluded from the dataset so that the customer product categories were emphasized in the analysis. By reintroducing the `'Channel'` feature to the dataset, an interesting structure emerges when considering the same PCA dimensionality reduction applied earlier to the original dataset.

Run the code block below to see how each data point is labeled either `'HoReCa'` (Hotel/Restaurant/Cafe) or `'Retail'` the reduced space. In addition, you will find the sample points are circled in the plot, which will identify their labeling.

```
In [20]: # Display the clustering results based on 'Channel' data
         vs.channel_results(reduced_data, outliers, pca_samples)
```



1.9.4 Question 12

- How well does the clustering algorithm and number of clusters you've chosen compare to this underlying distribution of Hotel/Restaurant/Cafe customers to Retailer customers?
- Are there customer segments that would be classified as purely 'Retailers' or 'Hotels/Restaurants/Cafes' by this distribution?
- Would you consider these classifications as consistent with your previous definition of the customer segments?

Answer:

Without knowledge of the channel feature the Gaussian Mixture Model clustered the data in a similar manner. The "actual" data seems to present what appears to be mislabled data or data

that occurs in the opposite cluster that would have been thought. It suggest that their are not clear bundaries, or that there are a number of “hybrid” companies in the data set.

However, in general this data is consistent with prior data sets, and clearly classify many if not mpost of the points as either a retailer or a restaurant.

> **Note**: Once you have completed all of the code implementations and successfully answered each question above, you may finalize your work by exporting the iPython Notebook as an HTML document. You can do this by using the menu above and navigating to
> **File -> Download as -> HTML (.html)**. Include the finished document along with this notebook as your submission.
